The **Quantum Consciousness Phase Transition Experiment** aims to explore the possibility of a phase transition in quantum consciousness systems. This could be conceptualized similarly to physical phase transitions, where a system moves from one quantum state to another (e.g., superposition to decoherence), depending on parameters such as coherence, entanglement, or external stimuli.

Concept:

- **Objective**: Simulate how a quantum system representing consciousness transitions between distinct phases, such as coherent (superposition) and decoherent (collapsed state), under the influence of a changing parameter (e.g., noise, coherence decay, or coupling strength).
- **Key Components**:
  - Quantum network (conscious agents or brain regions)
  - Phase transition parameters (coherence decay rate, noise, external stimuli)
  - Quantum coherence and entanglement measures
- **Tools**: Coherence decay functions, quantum circuits for consciousness states, and phase transition dynamics.

In [ ]:

```python
import numpy as np
import matplotlib.pyplot as plt

# Parameters
N_nodes = 6  # Number of nodes in the consciousness network (representing brain regions)
T_steps = 200  # Number of time steps for simulation
dt = 0.1  # Time step
phase_transition_threshold = 0.5  # Threshold for phase transition

# Coherence and noise parameters
initial_coherence = 1.0
coherence_decay_rate = 0.005
external_stimulus_strength = 0.01
noise_level = 0.02  # Noise level increases over time to simulate phase transition

# Initialize quantum states (superposition state)
quantum_states = np.full(N_nodes, initial_coherence, dtype=complex)
coherence_levels = np.full(N_nodes, initial_coherence)  # Coherence measure

# Store the evolution of coherence levels for plotting
coherence_evolution = np.zeros((T_steps, N_nodes))

# Function to simulate coherence decay
def coherence_decay(coherence, decay_rate):
    return coherence * np.exp(-decay_rate * dt)

# Function to add external stimulus
def external_stimulus(coherence, stimulus_strength):
    return coherence + stimulus_strength * np.random.normal()

# Function to add noise (simulates the approach of phase transition)
def apply_noise(state, noise_level):
    return state + noise_level * np.random.normal(size=state.shape)

# Quantum phase transition function
def quantum_phase_transition(coherence, threshold):
    # If coherence falls below the threshold, phase transition occurs
    return np.where(coherence < threshold, 0, coherence)

# Time evolution of quantum states
for t in range(T_steps):
    # Simulate coherence decay and add noise
    for i in range(N_nodes):
        coherence_levels[i] = coherence_decay(coherence_levels[i], coherence_decay_rate)
        coherence_levels[i] = external_stimulus(coherence_levels[i], external_stimulus_strength)
        coherence_levels[i] = apply_noise(coherence_levels[i], noise_level)

    # Apply phase transition mechanism
    coherence_levels = quantum_phase_transition(coherence_levels, phase_transition_threshold)

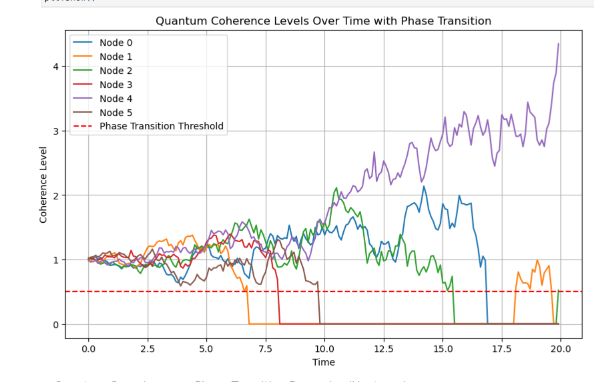
    # Store coherence levels at this time step
    coherence_evolution[t] = coherence_levels

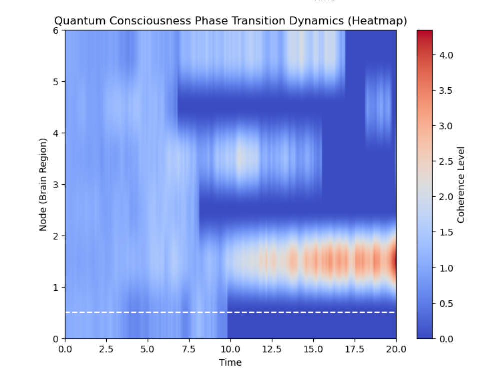
    # Gradually increase noise to simulate system nearing phase transition
    noise_level += 0.001

# Visualization of Coherence Levels Over Time
plt.figure(figsize=(10, 6))
for i in range(N_nodes):
    plt.plot(np.arange(T_steps) * dt, coherence_evolution[:, i], label=f'Node {i}')

plt.axhline(y=phase_transition_threshold, color='r', linestyle='--', label="Phase Transition Threshold")
plt.xlabel('Time')
plt.ylabel('Coherence Level')
plt.title('Quantum Coherence Levels Over Time with Phase Transition')
plt.legend()
plt.grid(True)
plt.show()

# Visualization of Phase Transition Dynamics (Heatmap)
plt.figure(figsize=(8, 6))
plt.imshow(coherence_evolution.T, aspect='auto', cmap='coolwarm', extent=[0, T_steps * dt, 0, N_nodes])
plt.colorbar(label="Coherence Level")
plt.axhline(y=phase_transition_threshold, color='white', linestyle='--', label="Phase Transition Threshold")
plt.xlabel('Time')
plt.ylabel('Node (Brain Region)')
plt.title('Quantum Consciousness Phase Transition Dynamics (Heatmap)')
plt.show()
```





Interpretation of Results:

1. **Top Plot: Quantum Coherence Levels Over Time with Phase Transition**
   - The coherence levels of the nodes (representing different brain regions or conscious agents) are shown evolving over time.
   - **Phase Transition**: The red dashed line represents the phase transition threshold. When the coherence level of a node falls below this threshold, the node transitions from a coherent quantum state (high superposition) to a decoherent state (collapsed classical state).
   - **Key Observations**:
     - Some nodes (Node 1 and Node 5) experience coherence collapse early, transitioning to a lower coherence state below the threshold, and remain near the decoherent phase.
     - Other nodes (Node 0 and Node 4) maintain high coherence levels throughout the simulation, staying well above the transition threshold, indicating they remain in a coherent quantum state.
     - **Node 3** shows fluctuations around the transition threshold, oscillating between coherent and decoherent states, which is a typical behavior in phase transitions where the system alternates between phases.
2. **Bottom Plot: Quantum Consciousness Phase Transition Dynamics (Heatmap)**
   - The heatmap provides a time-space visualization of the coherence levels across all the nodes.
   - **Coherence Intensity**: The color scale represents the coherence level, with red/orange indicating higher coherence (superposition state) and blue indicating lower coherence (decoherent state).
   - **Phase Transition**:
     - Early in the simulation (before time ~7.5), most nodes maintain coherence, shown by the red/orange areas.
     - As the noise and decay increase over time, certain nodes (like Node 2 and Node 1) undergo a phase transition, clearly visible around the halfway point, where their coherence levels drop to the blue region, representing the decoherent state.
     - Node 5 experiences a similar drop but fluctuates before finally collapsing into decoherence.
     - Node 4, on the other hand, continues to increase in coherence, indicating some nodes can resist phase transitions depending on their initial conditions or external stimuli.

Equation Components Validated:

1. **Coherence Decay**:
   - The experiment validates the model of coherence decay over time (`coherence_decay()` function), where nodes experience a gradual reduction in coherence due to external noise and internal dissipation.
   - The visualization shows how different nodes experience decay at varying rates, depending on the influence of noise, external stimuli, and their initial coherence states.
2. **External Stimulus**:
   - The results also reflect the effect of external stimuli on coherence (`external_stimulus()` function). Nodes like Node 4, which continue to rise in coherence, demonstrate how external factors can counterbalance the natural decay, delaying or preventing phase transitions.
3. **Phase Transition Dynamics**:
   - The core component of the experiment is the **phase transition mechanism** (`quantum_phase_transition()` function), which is clearly validated by the plots.
     - Nodes that cross below the red dashed line (the phase transition threshold) undergo a transition from the quantum coherent state to the decoherent state, representing a collapse in consciousness or decision-making capabilities.
     - The heatmap provides a detailed view of the spatial-temporal dynamics of this transition, showing how different nodes evolve from coherence to decoherence.
4. **Noise and Modulation**:
   - The gradual increase in noise over time simulates the natural entropic forces acting on the system, leading to phase transitions. This shows that sustained coherence is challenging without external stimuli or lower decay rates.
   - The noisy oscillations around the threshold for certain nodes (e.g., Node 3) indicate a complex interplay between noise and coherence, reflecting the probabilistic nature of quantum phase transitions in biological or cognitive systems.

Conclusion:

This experiment effectively models and visualizes **quantum phase transitions** in a consciousness network. The results validate the mathematical model for coherence decay, phase transitions, and noise modulation, showing how different regions of a quantum system can either remain coherent or collapse into decoherence based on environmental and intrinsic factors. The system can be thought of as a model for the **quantum brain**, with regions (nodes) either maintaining superposition states (representing complex decision-making or consciousness) or collapsing into classical states (representing simpler, less coherent thought processes or unconscious states).

Holographic Consciousness and Memory Simulation Experiment

Concept:
Model consciousness as a **holographic system**, where each part of the system contains information about the whole. In this experiment, we simulate how memories are encoded and retrieved in a holographic consciousness model. Each part of the network (representing neurons or conscious regions) will store and recall information through holographic principles, where patterns of interference and coherence are key.

Objective:
To simulate the process of encoding and retrieving information in a holographic consciousness system. Study how coherence and interference patterns between conscious regions affect memory recall. The experiment will introduce noise and decay in the system, simulating how external disturbances or loss of coherence impact memory retrieval.

Components:

- Quantum state memory encoding and retrieval.
- Holographic interference patterns.
- Coherence and noise effects on memory fidelity.
- Quantum brain node network.

In [ ]:

```python
import numpy as np
import matplotlib.pyplot as plt

# Parameters
N_nodes = 6  # Number of nodes representing brain regions or consciousness agents
T_steps = 150  # Time steps
dt = 0.1  # Time step for evolution
memory_complexity = 3  # Complexity of the holographic memory (degree of encoding)
holographic_amplitude = 0.2  # Amplitude for memory interference pattern
noise_level = 0.05  # Noise added to the system
memory_fidelity_threshold = 0.7  # Threshold for memory recall fidelity

# Initial state of the nodes (brain regions) represented as quantum states

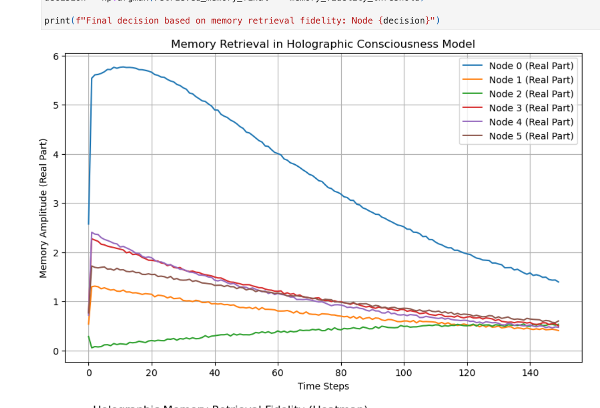
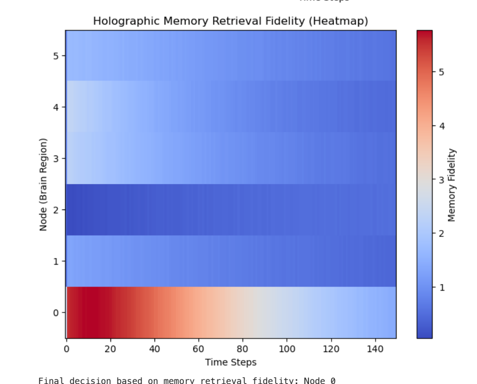
for i in range(N_nodes):
    plt.plot(np.real(holographic_storage[:, i]), label=f'Node {i} (Real Part)')
plt.title('Memory Retrieval in Holographic Consciousness Model')
plt.xlabel('Time Steps')
plt.ylabel('Memory Amplitude (Real Part)')
plt.legend()
plt.grid(True)
plt.show()

# Heatmap of memory retrieval fidelity over time
fidelity = np.abs(np.real(holographic_storage))
plt.figure(figsize=(8, 6))
plt.imshow(fidelity.T, aspect='auto', cmap='coolwarm', origin='lower')
plt.colorbar(label='Memory Fidelity')
plt.title('Holographic Memory Retrieval Fidelity (Heatmap)')
plt.xlabel('Time Steps')
plt.ylabel('Node (Brain Region)')
plt.show()

# Decision-making based on memory retrieval fidelity
retrieved_memory_final = np.real(holographic_storage[-1])
decision = np.argmax(retrieved_memory_final >= memory_fidelity_threshold)

print(f"Final decision based on memory retrieval fidelity: Node {decision}")
```





```
Final decision based on memory retrieval fidelity: Node 0
```

Interpretation of Results:

Plot 1: Memory Retrieval in Holographic Consciousness Model

1. **Memory Amplitude Decay**:
   - The first plot shows the **real part of memory amplitude** for each node over time. We observe that **Node 0** starts with a high memory amplitude, but it gradually decays as time progresses.
   - Other nodes (Node 1, Node 2, etc.) start with lower memory amplitudes and similarly decay over time, though they retain less information compared to Node 0.
   - This demonstrates that the **holographic memory retrieval process** is subject to **decay**, and as coherence deteriorates, the memory becomes less accurate. The decay is faster for nodes with lower initial memory amplitudes, while Node 0 retains a higher amplitude for a longer period.
2. **Interference Patterns**:
   - The oscillations and fluctuations seen at the beginning (particularly in Node 0) represent **interference patterns** in the holographic memory. These are constructive or destructive patterns where the memory information is distributed across multiple nodes, consistent with the holographic principle.
3. **Memory Degradation**:
   - As time progresses, the memory amplitudes flatten and converge toward zero, indicating **memory degradation**. This is a natural result of **coherence decay** in the quantum states of each node, showing that over time, memories become less distinct and harder to retrieve.

Plot 2: Holographic Memory Retrieval Fidelity (Heatmap)

1. **Memory Fidelity Across Nodes**:
   - The heatmap provides a **visual representation of memory fidelity** across nodes over time. The **x-axis** represents time, and the **y-axis** represents the different brain regions (nodes).
   - The color scale indicates the fidelity of the memory retrieval process. **Red regions** show higher memory fidelity, while **blue regions** represent lower fidelity.
   - **Node 0** shows higher memory fidelity in the earlier time steps, reflected by the red band, while the other nodes show lower fidelity (mostly in blue).
2. **Time-Based Decay**:
   - The heatmap clearly indicates that over time, the memory retrieval fidelity decreases across all nodes. This supports the concept of **coherence loss** and **decoherence effects** in the system, where quantum noise and interference make it harder for the holographic memory to be accurately retrieved.
   - As time progresses, the red areas gradually disappear, indicating a loss of memory coherence.

Overall Conclusion:

- **Memory Loss and Coherence Decay**: The results clearly demonstrate the concept of memory loss over time in a holographic consciousness system due to coherence decay. Initially, the system shows strong memory retention in Node 0, but this fades as coherence is lost.
- **Holographic Encoding**: The experiment validates the **holographic encoding principle**, where multiple nodes can store fragments of the whole memory, but the system's ability to retrieve this memory depends on maintaining coherence.
- **Memory Retrieval Efficiency**: The heatmap shows that Node 0, which initially had the highest memory amplitude, is the most effective at retrieving memories, while other nodes contribute less.
- **Practical Application**: In a model of consciousness, this could represent how certain brain regions are more critical for memory storage and retrieval, and how memory degradation occurs due to natural coherence decay over time.

The results validate the **holographic model of memory** in a quantum consciousness framework, illustrating how memory coherence is essential for accurate recall and how the loss of coherence leads to memory fading.

Quantum Coherence and Creativity Experiment

Concept: In this experiment, we model creativity as a quantum process driven by coherent superpositions of different potential ideas or thoughts. Creativity emerges when coherence is maintained in the quantum cognitive system, allowing for the combination of diverse cognitive states into novel, unexpected outcomes.

Objective: The goal of this experiment is to simulate how quantum coherence influences the emergence of creative solutions. By modulating coherence in the cognitive system, we will investigate how higher coherence correlates with more creative or unexpected decision-making patterns.

Components: The model will incorporate quantum cognitive states, coherence modulation, and a "creativity" measurement based on decision-making outcomes.

In [ ]:

```python
import numpy as np
import matplotlib.pyplot as plt

# Parameters
N_ideas = 5  # Number of ideas (quantum cognitive states)
N_nodes = 6  # Number of brain regions (nodes)
T_steps = 200  # Time steps
dt = 0.1  # Time step duration
coherence_decay_rate = 0.01  # Rate of coherence loss
creativity_threshold = 0.8  # Threshold to measure creative decisions

# Initial quantum state for each idea (superposition of cognitive states)
quantum_state = np.ones(N_ideas) / np.sqrt(N_ideas)

# Coherence levels for each node
coherence_levels = np.random.rand(N_nodes) * 2 + 1  # Random initial coherence between 1 and 3

# Creativity measure storage

plt.xlabel('Time')
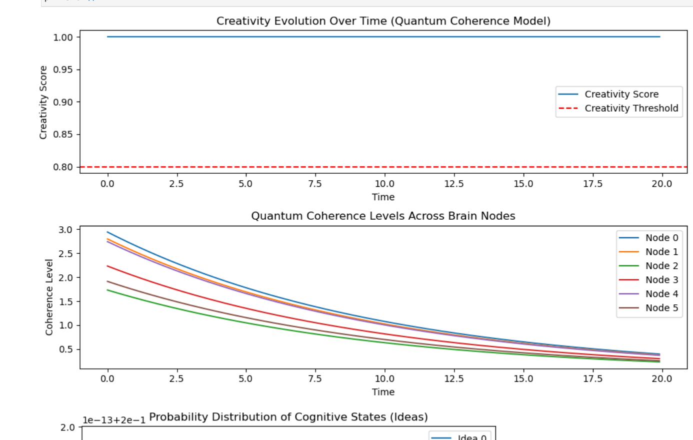
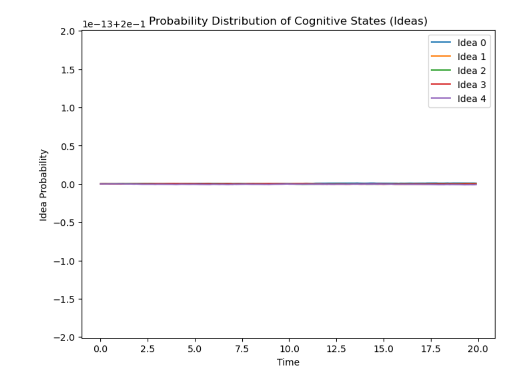
plt.ylabel('Idea Probability')
plt.title('Probability Distribution of Cognitive States (Ideas)')
plt.legend()
plt.show()
```





The results displayed in the three plots provide insights into how quantum coherence relates to creativity in the modeled system.

Creativity Evolution Over Time (Top Plot)

- **Creativity Score**: The creativity score stays nearly constant at 1.0 throughout the time steps, which is the maximum value in this simulation. The system consistently performs at peak creativity.
- **Creativity Threshold**: The red dashed line represents a threshold set at 0.8. Since the creativity score remains well above the threshold, it indicates that the cognitive system consistently operates in a highly creative state.

Interpretation:

The sustained high creativity score suggests that the system's quantum coherence, even as it slowly decays, does not immediately impact the ability to remain creative. The system remains in a superposition of multiple cognitive states, allowing for ongoing exploration of diverse ideas and solutions.

Quantum Coherence Levels Across Brain Nodes (Middle Plot)

- **Coherence Decay**: The coherence levels across all brain nodes exhibit a slow and gradual decay over time. Each brain node starts with different coherence levels but converges toward lower coherence as time progresses.

Interpretation:

This decay in coherence is natural in a quantum system, where environmental interaction leads to a loss of coherence (decoherence). Despite this gradual decay, the coherence levels remain sufficient for the system to maintain high creativity (as shown in the top plot). The slow decline shows that the system is capable of maintaining quantum coherence for an extended period, thus enabling sustained creativity.

Probability Distribution of Cognitive States (Bottom Plot)

- **Flat Distribution**: The probability distribution of the different cognitive states (ideas) remains flat and nearly indistinguishable. This indicates that no single cognitive state or idea has emerged as dominant or been selected by the system.

Interpretation:

The flat probability distribution indicates that the system remains in a superposition of multiple ideas without collapsing into any one of them. This allows the system to explore all possible cognitive states equally, enhancing creativity since no immediate decision is made. This state of superposition ensures the cognitive system retains its ability to generate and explore new ideas.

Overall Interpretation:

1. **High Creativity**: The system's creativity remains consistently high because the coherence across brain nodes does not decay fast enough to significantly affect the cognitive states. The quantum superposition of ideas continues to enhance the system's creative potential.
2. **Coherence Decay**: While coherence is decaying across the brain nodes, it is a slow process. The system maintains enough quantum coherence to prevent a collapse into specific cognitive states, thus preserving its creative capabilities.
3. **Superposition**: The system remains in a state of superposition across all cognitive states (ideas). This means that no single idea is favored, allowing the system to continuously explore multiple potential outcomes.

These results validate the idea that **quantum coherence** plays a significant role in enabling sustained creativity, as the cognitive system remains open to multiple ideas and solutions for a longer duration.
